
Rows: Leiden clusters of excitatory neurons, labeled with their most common subtype, sorted by percent high-pathology cells.
Switching: the cell's GMM label disagrees with its Disease.Group label in more than 10% but at most 90% of RecurSieve iterations (GMM 1 matched to high).
Matching labels (green square): the cell's final GMM label equals its own Disease.Group label (GMM 1 = high); equal orange and black percentages do not imply this.
